1 Overview

This vignette provides an introduction to the **GPATree** package. R package **GPATree** implements GPA-Tree, a novel statistical approach to prioritize genome-wide association studies (GWAS) results while simultaneously identifying the combinations of functional annotations associated with risk-associated genetic variants. GPA-Tree integrates GWAS summary statistics and functional annotation data within a unified framework, by combining a decision tree algorithm (CART)(Leo et al. 1984) within the hierarchical model.

The package can be loaded with the command:

```
> library(GPATree)
```

This vignette is organized as follows. Sections 2.1 and 2.2 illustrate the recommended **GPATree-ShinyGPATree** workflow, which provides convenient and interactive genetic data analysis interface. Advanced users might also find Sections 2.3.1 – 2.3.3 useful and these command lines can be used for integrating GPA-Tree as part of the more comprehensive genetic data analysis workflow, for example.

Please feel free to contact Dongjun Chung at chung.911@osc.edu for any questions or suggestions regarding the ‘**GPATree**’ package.

2 Workflow

In this vignette, we illustrate the GPA-Tree analysis workflow, using the simulated data provided as the **GPATreeExampleData** in the **GPATree** package. In the simulated data, the number of SNPs is set to

$M = 10,000$ and the number of functional annotations is set to $K = 10$. The GWAS association p -values and the binary functional annotation information are stored in `GPATreeExampleData$gwasPval` and `GPATreeExampleData$annMat`, respectively. The number of rows in `GPATreeExampleData$gwasPval` is assumed to be the same as the number of rows in `GPATreeExampleData$annMat`, where the i -th ($i = 1, \dots, M$) row of `gwasPval` and `annMat` correspond to the same SNP.

```
> data(GPATreeExampleData)
> dim(GPATreeExampleData$gwasPval)
[1] 10000      1
> head(GPATreeExampleData$gwasPval)
      P1
SNP_1 0.7454
SNP_2 0.4894
SNP_3 0.6026
SNP_4 0.1496
SNP_5 0.2538
SNP_6 0.3161
> dim(GPATreeExampleData$annMat)
[1] 10000      10
> head(GPATreeExampleData$annMat)
      A1 A2 A3 A4 A5 A6 A7 A8 A9 A10
SNP_1  1  0  0  0  0  1  0  0  0  1
SNP_2  1  0  0  0  0  0  0  0  0  0
SNP_3  1  0  0  0  0  0  0  0  0  1
SNP_4  1  0  0  0  0  0  0  0  0  0
SNP_5  1  0  0  0  1  1  0  0  0  0
SNP_6  1  0  0  0  0  1  0  0  0  0
```

2.1 Fitting the GPA-Tree Model

We can fit the GPA-Tree model using the GWAS association p -values (`GPATreeExampleData$gwasPval`) and functional annotation data (`GPATreeExampleData$annMat`) described above, using the code shown below.

```
> fit.GPATree <- GPATree(gwasPval = GPATreeExampleData$gwasPval,
+                        annMat = GPATreeExampleData$annMat,
+                        initAlpha = 0.1,
+                        cpTry = 0.005)
```

```
> fit.GPATree
Summary: GPATree model results (class: GPATree)
```

Data summary:

```
  Number of GWAS data: 1
  Number of Annotations: 10
  Number of SNPs: 10000
  Alpha estimate: 0.4999
```

Functional annotation tree description:

```
      local FDR A4 A2 A1 A3
LEAF 1    0.9849  0  0  -  -
LEAF 2    0.9834  0  1  0  -
LEAF 3    0.0203  0  1  1  -
LEAF 4    0.9850  1  -  -  0
```

```
LEAF 5      0.0154  1  -  -  1
```

2.2 ShinyGPATree

The following command can be used to initialize the ShinyGPATree app. ShinyGPATree allows for interactive and dynamic investigation of disease-risk-associated SNPs and functional annotation trees using R Shiny.

```
> ShinyGPATree(fit.GPATree)
```

2.3 Advanced use

2.3.1 Prunning GPA-Tree model fit

The following command will prune the GPA-Tree model using any cp value between 0 and 1.

```
> fit.GPATree.pruned <- prune(fit.GPATree, cp)
```

2.3.2 Functional annotation tree

The following command will plot the GPA-Tree functional annotation tree and provide information about the leaves (terminal nodes) in the tree.

```
> plot(fit.GPATree)
```

```
> leaf(fit.GPATree)
      local FDR A4 A2 A1 A3
LEAF 1      0.9849  0  0  -  -
LEAF 2      0.9834  0  1  0  -
LEAF 3      0.0203  0  1  1  -
LEAF 4      0.9850  1  -  -  0
LEAF 5      0.0154  1  -  -  1
```

2.3.3 Association mapping

Based on the fitted GPA-Tree model, we can make statistical inference about SNPs by identifying: (1) risk-associated SNPs and (2) the leaves of the GPA-Tree model in which the risk-associated SNP are located in using the code below.

```
> assoc.SNP.GPATree <- assoc(fit.GPATree,
+                             FDR = 0.05,
+                             fdrControl="global")
> head(assoc.SNP.GPATree)
      P1  leaf
SNP_1  0 LEAF 1
SNP_2  0 LEAF 1
SNP_3  0 LEAF 1
SNP_4  0 LEAF 1
SNP_5  0 LEAF 1
SNP_6  0 LEAF 1
> table(assoc.SNP.GPATree$P1)

0    1
```

```

8542 1458
> table(assoc.SNP.GPATree$leaf)

LEAF 1 LEAF 2 LEAF 3 LEAF 4 LEAF 5
7198    700    701    700    701
> table(assoc.SNP.GPATree$P1, assoc.SNP.GPATree$leaf)

      LEAF 1 LEAF 2 LEAF 3 LEAF 4 LEAF 5
0      7154    695      0    693      0
1       44      5    701      7    701

```

The `GPATree_assoc` function returns two columns. The first column contains binary values where 1 indicates that the SNP is associated with the phenotype and 0 indicates otherwise. The second column provides information regarding the leaf in which the SNP is located in the GPA-Tree plot. The `GPATree_assoc` allows both local (`fdrControl="local"`) and global FDR controls (`fdrControl="global"`) and users can set the threshold using the argument 'FDR'. For `GPATreeExampleData`, GPA-Tree model identified 1458 risk SNPs at the nominal global FDR level of 0.05.
